

Prompt 1

Prompt:

I want to add a persistent global statistics feature to my PHP Battleship game that tracks total wins, total losses, total shots fired, and total games played. Stats should be stored in a JSON file on the server and persist across refresh and Apache restart. The server must handle reading and writing. The client should only fetch and display totals.

Why I asked this:

I needed true persistence beyond session memory. Stats had to survive refresh and Apache restart.

Issue discovered:

The JSON file was updating correctly on the server, but the UI did not update after New Game or Restart actions because stats were only fetched once on page load.

Prompt 2

Prompt:

Adjust app.js to re fetch global stats on a new game or restart game action.

Why I asked this:

Because stats were persisting correctly in JSON, but the UI was stale unless the page was refreshed. I needed the client to pull updated totals after reset actions.

Issue discovered:

There were no further issues after this change. Stats updated correctly and the UI stayed in sync.

Prompt 3

Prompt:

I want to add a Limited Ammo feature to my PHP Battleship game. The player should have a fixed number of shots and each valid shot should decrement ammo. If ammo reaches zero before all ships are sunk, the game should end with a loss. Ammo must be stored and

enforced on the server, not in JavaScript. The client should only display the remaining ammo.

Why I asked this:

I wanted a second feature that required additional state tracking and strict server side rule enforcement within the existing turn based system.

Issue discovered:

No issues.
